SOURCES FOR WATER SUPPLY IN MISSISSIPPI	25

INTRODUCTION

Section 106(e) of the Clean Water Act requires that each state monitor the quality of its surface and groundwater resources and report the status to Congress every two years in its State 305(b) Report. This section of the 305(b) Report addresses the groundwater quality in Mississippi. Groundwater resources provide over 90% of Mississippi's drinking water supply. The 1200 public water systems operating in the state use 3500 wells and four surface water intakes. Because of this reliance on groundwater, the State has a vested interest in its protection as evidenced in this report.

Over the years, the Environmental Protection Agency (EPA) has made various revisions to the reporting requirements associated with the groundwater section of the 305(b) Report. These changes signaled an attempt by the EPA to not only address relevant groundwater issues of concern or interest but also to obtain aquifer-specific data that can be used for comparison sake. There are 16 major aquifers and numerous minor aquifers distributed throughout Mississippi. Unfortunately, this large number of aquifers makes providing aquifer-specific data in the report cumbersome.

The overall quality of the groundwater resources in Mississippi remains very good. Natural coloration associated with certain aquifers is the most notable groundwater quality issue in the state. Extensive contamination of aquifers in the state or incidents of public water systems being impacted by groundwater contamination are uncommon. The sporadic "boil water" notices periodically issued in the state are usually the result of system maintenance issues or unforeseen natural disasters. Another issue is the relatively large number of small rural water associations operating in the state that are often plagued with compliance issues.

ASSESSMENT OF GROUNDWATER QUALITY

EPA guidelines for the 305(b) Report encourage the use of the best available data in reflecting the quality of the groundwater resources. To provide as accurate and representative assessment of the groundwater quality in Mississippi as possible, the information in this report contains data compiled from the Mississippi Department of Environmental Quality (MDEQ), the Mississippi State Department of Health (MSDH), and the U. S. Geological Survey (USGS).

Groundwater Quality Standards

In November 1991, MDEQ adopted groundwater quality standards equivalent to the EPA established drinking water standards or Maximum Contaminant Levels (MCLs). These standards apply to all of the groundwater in Mississippi that meets the EPA's

3

definition of underground sources of drinking water (USDW), which is defined as water that “contains fewer than 10,000 mg/l total dissolved solids.” However, the State standard did allow for an exemption of certain water-bearing geologic units capable of yielding only extremely low volumes of water.

The standards also establish a procedure to calculate groundwater quality standards for types of constituents that may not be included on the EPA list of MCLs.

Mississippi Agricultural Chemical Groundwater Monitoring Program

The Mississippi Agricultural Chemical Groundwater Monitoring (AgChem) Program was initiated in March 1989 for the purpose of determining if the use of agricultural chemicals is impacting groundwater quality in Mississippi. Thus far, the sampling of over 1,800 wells throughout the state does not indicate any significant impacts directly attributable to agricultural practices.

During 2012, the AgChem Program collected samples from a total of 83 wells across the state, including 54 private water wells and 29 large-capacity irrigation and fish culture wells located in the Mississippi Delta.

U. S. Geological Survey

The USGS has sampled water wells in Mississippi since the early 1900's. Most of the USGS sampling has involved analysis of inorganic parameters to characterize the basic types of groundwater found in the various aquifers across the state. These sampling efforts helped establish that most of the groundwater in Mississippi can be characterized as a soft sodium or calcium bicarbonate type. Although the USGS has been involved in previous surface water investigations to identify pesticides in surface water bodies in the state, the agency has not actively pursued similar groundwater studies until fairly recently.

National Water Quality Assessment (NAWQA) Program – Congressional funding in the late 1980s enabled the USGS to initiate the NAWQA Program, designed to investigate the status and trends of the water quality in the streams, rivers, and groundwater supplies found throughout the nation. After dividing the country into 60 study areas or units, the USGS began phasing in this project in 1991. Initially, 15 NAWQA study units across the nation were designated for investigation by the USGS, including one that encompassed parts of six states in the Mississippi Embayment. A significant area of northern Mississippi was contained in this investigation, including the Mississippi Delta region, the preeminent agricultural area in the state. The study involved the sampling of 14 wells pumping from the shallow MRVA, widely used for irrigation and fish culture in the Delta, or various deeper Tertiary aquifers that provide drinking-water supply throughout northern Mississippi. The results reported by the USGS indicate no exceedances of MCLs on any samples obtained from the Tertiary aquifers in the state. The study also concluded that even the shallow alluvial aquifer underlying the Mississippi Delta had not been adversely impacted by the application of significant amounts of pesticides in the region. The reported results from the Mississippi Embayment study closely mimic those reported for MDEQ's AgChem Program. Cycle II of the NAWQA program began in 2001 and focuses on regional assessments of water-quality conditions and trends.

During Cycle II, three new groundwater investigations began in Mississippi. Three sites were established in the Mississippi Delta region to investigate the fate and transport of agricultural chemicals in surface and groundwater. Two wells were sampled in northwestern Bolivar County in an area used for corn and cotton production. A groundwater infiltration study was conducted in a soybean field in Bolivar County, and a groundwater/surface-water interaction study was conducted in northeastern Washington County adjacent to the Bogue Phalia at US Highway 82.

A 30-well network was established over the coastal portions of MS, AL, and FL to monitor the quality of water in domestic supply wells screened in aquifers of the Coastal Lowlands aquifer system. Sixteen of the sampled wells were located in Hancock, Pearl River, Lamar, Stone, Harrison, Jackson, George, and Perry Counties.

A 30-well network was established in MS and TN to investigate the quality of water in the out-crop areas of the middle Claiborne aquifer. Thirteen wells used for drinking water were sampled in the Sparta aquifer in MS.

The 60 designated study units in the NAWQA investigation cover other parts of Mississippi as well. The ongoing Acadian-Pontchartrain investigation is centered primarily in Louisiana but covers parts of five counties in southwestern Mississippi. Another study underway focuses on the Mobile River Basin and encompasses a large area along the eastern side of the state associated with the Tombigbee River Basin. Seven wells in Mississippi are scheduled for sampling during the Mobile River Basin investigation. Reports on the two studies are available online at pubs.er.usgs.gov.

Mississippi State Department of Health

The Safe Drinking Water Act (SDWA) allows States to seek EPA approval or primacy to administer their own Public Water System Supervision (PWSS) Programs, often referred to as the drinking water program. To receive program primacy, the EPA must determine that a State meets certain requirements laid out in the SDWA and complementary regulations. Some of these requirements include the adoption of State drinking water regulations that are at least as stringent as the Federal regulations and a demonstration that a State can enforce the program requirements. Mississippi assumed administration of its PWSS Program in 1974 when the Mississippi State Department of Health's (MSDH) Bureau of Public Water Supply became the primacy agency. This agency is responsible for ensuring that safe drinking water is provided to the 96% of the state's population who rely on the 1,200 public water systems (PWSs) and their corresponding 3,500 wells operating in Mississippi (Figures II and III).

The EPA also regulates the frequency with which PWSs monitor their water supply for contaminants and report the corresponding analytical results. PWSs are required to monitor and verify that the levels of contaminants present in their drinking water supply do not exceed established MCLs. In Mississippi, most PWSs submit all of their samples to the MSDH for analysis at the state laboratory. The laboratory annually processes and analyzes over 50,000 water samples submitted for microbiological analysis as well as hundreds of samples for lead and copper, nitrate/nitrite, various inorganic constituents, volatile organic compounds (VOCs), total trihalomethanes (TTHMs), haloacetic acids, and bromates. The overall compliance rate of PWSs

in Mississippi is generally very high because of the predominant use of confined aquifers for drinking water supplies. Most of the PWSs have been granted a waiver from monitoring for the synthetic organic compounds (pesticides) based on previous studies, vulnerability assessments, and chemical use data.

Primacy States are required to submit data quarterly to the EPA via the Safe Drinking Water Information System (SDWIS), an automated database maintained by the Federal agency. Some of the data submitted include PWS inventory information, monitoring/compliance information, and enforcement activity related to any system violations. The SDWA also requires States to provide the EPA with an annual report detailing violations of established MCLs by operating PWSs.

The 1996 Amendments to the SDWA require that every community water system provide its customers with a brief annual water quality report. A system's Consumer Confidence Report (CCR) should explain the nature of any violation, its potential health effects, and the steps being taken to correct the violation. The CCRs often include educational material and also provide information related to the Source Water Assessment Program.

Summary of Groundwater Quality

The information included in Table I summarizes the groundwater quality data compiled by the MDEQ. The reporting period for the MDEQ data is 1990 through 2012. The reported parameters include those specifically requested by the EPA for the 305(b) Report. The only MCL violation for a public water system was for fluoride and it is being monitored quarterly.

Table I. MDEQ Analytical Results

Aquifer	# Wells Sampled	NO3 0-5 mg/l	NO3 5-10 mg/l	NO3 >10 mg/l	VOCs >MCL	SOCs >MCL

GROUNDWATER CONTAMINATION IN MISSISSIPPI

The aquifers used for drinking water supply in Mississippi generally are confined to some extent by layers of clay that prevent widespread instances of groundwater contamination. Most of the documented cases of groundwater contamination in Mississippi have involved shallow unconfined aquifers that remain widely used in some areas of the state as domestic drinking water sources.

Potential Sources of Contamination

The primary sources of groundwater contamination in Mississippi typically can be traced to leaking underground storage tanks (USTs) holding petroleum-based products and faulty septic systems. Another problem of note in areas of the state where petroleum exploration and production have been prevalent is localized brine (saltwater) contamination of shallow aquifers. Many of the past problems associated with the oil and gas industry have been corrected with the adoption of more stringent state regulations. Groundwater contamination involving hazardous waste has been detected at various commercial and industrial facilities across the state as well. These facilities often cover such relatively large tracts of land that the associated contamination plumes are contained within their property boundaries. Table II lists the major sources of groundwater contamination and also other perceived sources of contamination in Mississippi. The location of selected potential contaminant sources, Brownfields sites, and groundwater remediation sites involving the Comprehensive Environmental Response and Compensation, and Liability Act (CERCLA) Program are identified in Figures IV and V.

Table II. Major Sources of Ground Water Contamination

Contaminant Source	Ten Highest Priority Sources	Factors Considered in Selecting a Contaminant Source	Contaminants

Clean Up of Contamination

Accidents, spills, leaks and past improper disposal and handling of hazardous materials and waste have resulted in a number of sites that have contaminated land, water, and air. Through five programs, the Brownfields Program, the Uncontrolled Sites Program, the Voluntary Evaluation Program (VEP), the CERCLA Program, and the Underground Storage Tanks (UST) Program, the staff of the Groundwater and Remediation Division (GARD) is responsible for the protection of human health and the environment by overseeing the assessment and remediation of contaminated sites in Mississippi.

Brownfields

Three Brownfield Agreements were reached in 2011, with the redevelopment of the former Amoco/Afta Brownfield site serving as this year's highlight in both total investment and job creation. The Elevance Renewable Sciences Inc., creator of high-performance renewable specialty chemicals for use in personal care products, detergents, plastics, and lubricants, was able to acquire the former Amoco/Afta Brownfield site in Natchez with the assistance of the Mississippi Department of Environmental Quality (MDEQ) and the Mississippi Development Authority (MDA). Through the Mississippi Industry Incentives Financing Revolving Fund, MDA provided assistance for upgrades at the Natchez/Adams County Port, as well as a \$25 million loan to the Elevance. Meanwhile, MDEQ, through the Mississippi Brownfields Program, reached a Brownfield Agreement with Delta Biofuels, Inc. that addressed liability concerns related to legacy environmental conditions at the facility. The company is converting the facility to a biorefinery and derivatives operation that will involve an investment of more than \$225 million and will create 165 full-time jobs over the next five years, in addition to 300 construction jobs. The financial assistance from MDA and the Brownfield Agreement, approved by the Mississippi Commission on Environmental Quality, paved the way for the brownfield redevelopment project to materialize.

Underground Storage Tanks

The goal of the Underground Storage Tanks (UST) Program is to protect groundwater from leaking underground storage tanks. To meet this goal there is a two-pronged approach. First, a compliance program inspects UST facilities in order to ensure the systems do not leak. In Mississippi, the UST compliance personnel are responsible for ensuring approximately 8,449 tanks at 3,173 facilities have the appropriately maintained equipment in order to protect the groundwater. Secondly, in the event of a release, there is a fund available for eligible tank owners to help in the assessment and cleanup resulting from leaking USTs, The Mississippi Groundwater Protection fund began in 1987 and has committed \$150 million to eligible tank owners for the assessment and cleanup of sites contaminated from leaking USTs. The average fund commitment per site

has been \$148,900. At the end of 2010, the Mississippi Groundwater Protection Trust Fund had assessed 1,012 sites, completed assessment and/or remediation of 798 sites and had 214 active sites. This past fiscal year \$6.78 million were reimbursed to eligible tank owners. Also, this year 22 new sites were assessed and 20 sites were closed.

Additionally, using the Leaking Underground Storage Tanks Trust Fund (LUST)/American Recovery and Reinvestment Act (ARRA) funds, in 2010 the staff assessed and /or remediated another 29 sites and closed out 5 sites. State fiscal year expenditures were \$1.68 million.

The program also continued to do work utilizing the LUST Katrina Supplemental Funds to continue work on 11 of these sites and closed out an additional two sites. With the LUST Katrina Supplemental Funds the program has expended \$343,000 in state FY 2011.

Uncontrolled Sites

Over the past 12 months, GARD actively oversaw 169 sites. During that same timeframe, the number of sites brought to GARD's attention was 10, bringing the total number of sites in MDEQ's public record to 1,784 sites. Also, MDEQ issued "State No Further Action" (SNFA) letters for 14 of these sites that were evaluated and remediated to levels protective of human health and the environment. In addition, MDEQ issued Restrictive Use Agree Orders for one site, thereby allowing the sites to be reused with certain activity and use limitations. The staff continues to respond expeditiously to requests from MDOT and other governmental agencies for the review of environmental assessments and remediation of contaminated sites and those sites with economic development potential.

Voluntary Evaluation Program

Courthouse property was remediated to protective levels so the courthouse could be completed this past year., The Voluntary Evaluation Program (VEP) offers participants an opportunity to receive an expedited review of site characterization and remediation plans and reports for uncontrolled sites in which they have an interest. The VEP is funded entirely by these participants who pay for MDEQ's oversight costs. Typically, individuals involved in property transfers find the VEP attractive because of the expedited review process. There were 10 new VEP sites that joined the program this fiscal year.

Comprehensive Environmental Response, Compensation, and Liability Act

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) oversight of the site assessment and restoration of hazardous waste sites at federal facilities continues to be a large portion of the CERCLA Program.

Oversight is conducted at seven Department of Defense sites, a Department of Energy site (Salmon Test Site), a NASA facility (Stennis Space Center), and several formerly used defense sites. MDEQ is funded for this oversight work through agreements with the Department of Defense, the Department of Energy, and NASA. Through the grants from the Environmental Protection Agency, CERCLA staff performed preliminary assessments, site investigations and site inspections at hazardous waste sites for National Priority List (NPL) consideration, coordinated with EPA on emergency/removal projects at the Southern Pine Wood Preserving site, Wiggins and the Southeastern Wood Preserving site, Canton, and assisted the EPA with the oversight of the assessment and future remediation of four Superfund sites in the state – Sonford Products, Flowood; Davis Timber, Hattiesburg; American Creosote, Louisville; and Wood Treating, Picayune. At the present time it is estimated that the remediation costs for these four sites is approximately \$76 million. The state will ultimately have to pay 10 percent of these remediation costs. In addition, Red Panther Chemical, Clarksdale; Kerr-McGee (Tronox), Columbus; and Southeastern Wood, Canton, are being considered and evaluated for NPL listing, however there has been no estimation of remedial costs to date. The Red Panther Chemical, Clarksdale site is a potential responsible party (PRP) site and the responsible party(s) will be paying for the further assessment and remediation of the site. The Kerr-McGee (Tronox), Columbus site went into bankruptcy and further legal proceedings. The initial bankruptcy proceeding resulted in a Trust being set up that will provide some money toward the further assessment and remediation of the site. If ongoing legal proceedings by the EPA, U.S. Department of Justice, and many states are successful then a responsible party will pay for all of the assessment and remediation of this site and many other sites previously owned by Kerr-McGee in Mississippi and other states. The Southeaster Wood, Canton site does not have a potentially responsible party and if listed will require a 10% state match for the remediation costs.

RCRA Corrective Action

EPA Region 4 is responsible for 19 sites in the state that are under the jurisdiction of the Resource Conservation and Recovery Act (RCRA) Corrective Action Program. This program covers the cleanup of hazardous waste and hazardous constituents released from Solid Waste Management Units or Areas of Concern at regulated facilities. More than half of these facilities have achieved control of current human exposures and control of the migration of contaminated groundwater according to the EPA website.

Table III is a statewide summary of groundwater contamination source types and the number of sites for each source. The format of the table was established by the EPA, specifically for inclusion in the 305(b) Reports.

GROUNDWATER PROTECTION EFFORTS

The Mississippi Department of Environmental Quality (MDEQ) has received primacy from the EPA to administer the related Federal programs dealing with groundwater and surface water quality in the state. The Groundwater Planning Branch in MDEQ's Office of Land and Water Resources (OLWR) has the primary responsibility of coordinating groundwater (quality) protection efforts in Mississippi. Activities to prevent the contamination of drinking-water aquifers in the state have focused mainly on the implementation of the Wellhead Protection Program, completion of Source Water Assessment Program requirements, and addressing Source Water Protection Program related measures.

Wellhead Protection Program

Initial groundwater protection efforts by the Groundwater Planning Branch focused on the State Wellhead Protection Program (WHPP). This program conceptually was designed to identify and properly manage potential contaminant sources in Wellhead Protection Areas from which public water system (PWS) wells capture their water over a specific period of time. Demonstration projects for several high-priority PWSs in Mississippi resulted in the first local management plans being completed in the state by the mid-1990s. MDEQ used the success of these projects to spearhead interest in cross-program coordination of groundwater protection activities in Mississippi.

Since the mid-1990s, the Mississippi Rural Water Association has utilized a national EPA grant to fund a technician who has assisted MDEQ in the development and implementation of local Wellhead Protection management plans. Most of the WHPP activities over the past eight years have centered around Rural Water's efforts to develop management plans for at least 12 rural PWSs per year.

Source Water Assessment Program

The 1996 amendments to the Safe Drinking Water Act mandated states to develop and implement a Source Water Assessment Program (SWAP). The purpose of this program was to notify PWSs and customers regarding the relative susceptibility of their drinking-water supplies to contamination. Congress intended for these susceptibility assessments to encourage efforts that would enhance the protection of PWSs by managing identified potential contaminant sources of concern. In 1998, the Mississippi State Department of Health (MSDH) contracted with MDEQ to develop and administer the SWAP in Mississippi. Required elements of assessments include the following: (1) delineating Source Water Protection Areas around PWS wells; (2) inventorying potential

contaminant sources in the protection areas; (3) assigning susceptibility rankings to wells; and (4) notifying the public regarding the availability of SWAP information.

Assessments in Mississippi use the following rankings to notify PWSs of their relative susceptibility: (1) Higher, (2) Moderate, and (3) Lower. Most of the public groundwater system wells in the state have received a Moderate ranking (63%), while 29% have received Lower rankings and only 8% have received Higher susceptibility rankings. Some of the criteria considered when assigning these rankings to public groundwater systems include aquifer confinement; MSDH minimum well design criteria; potential contaminant sources identified within the delineated Source Water Protection Area; and abandoned wells within the protection area.

The size of a Source Water Protection Area is based on eight delineation scenarios that were developed using EPA's Wellhead Protection Area (WHPA code) computer program. The different scenarios are a result of countless computer modeling runs and an extensive data review of aquifer characteristics and well data from the USGS and MDEQ's Office of Geology and OLWR. The eight developed delineation scenarios incorporate differing model input parameters, including well discharge, aquifer porosity and transmissivity, aquifer thickness, and time. The approved pumping scenarios are arranged according to well discharge ranges with larger pump rates corresponding to larger Source Water Protection Areas.

Assessments of all public groundwater systems and the three public surface water systems operating in the state have been completed. After MDEQ mailed the prepared assessment reports to the systems, it became their responsibility to notify their customers that a SWAP report was available for review upon request. As another reminder, the EPA required the annual Consumer Confidence Report (CCR) prepared by systems to include a reference regarding the SWAP report and a brief summary of the assessment findings.

The SWAP reports and corresponding maps of delineated Source Water Protection Areas are available online at the MDEQ website: <http://landandwater.deq.ms.gov/swap>. As a result of recent MDEQ regulatory changes, all new PWS wells now require that preliminary assessments be performed by MDEQ prior to the issuance of groundwater withdrawal permits. These preliminary assessments allow the suitability of proposed well sites to be screened prior to the drilling and completion of PWS wells.

Source Water Protection Strategy

Mississippi's Source Water Protection Strategy for PWS wells using unconfined aquifers involves the integration/coordination of protection efforts with various environmental regulatory programs within MDEQ, such as UST, RCRA,

CERCLA, and Brownfields/Uncontrolled Sites, as well as the MSDH. The implementation of this strategy is initiated when the corresponding regulatory programs are provided a Source Water Assessment analysis of a PWS well from the Groundwater Planning Branch. This direct cross-program involvement should help to ensure contaminant plumes do not degrade shallow groundwater sources used for public water supply. The strategy will be considered complete after MDEQ meets with representatives of systems to explain pertinent protection measures.

The protection strategy for public groundwater systems using deeper confined wells focuses on the hydrogeologic confinement (vulnerability) of their production aquifers. Adequate aquifer confinement is generally assumed if an overlying confining unit of clay is at least 30 feet in thickness and/or the corresponding potentiometric surface (head) extends at least 10 feet above the screened aquifer. The implementation of this strategy is considered complete when the confinement is verified and a system is notified of any abandoned (unplugged) wells that may pose public health issues.

The Source Water Protection Strategy for the four surface water intakes used in the state involves the integration of public drinking-water protection into MDEQ's Basin Management Approach that is designed to protect and restore the quality of Mississippi's surface water resources. This integration component was well received by the two relative Basin Management Teams which incorporated extra protection measures into their management plans to complete the strategy. EPA Region IV and the Tennessee Valley Authority are assisting MDEQ with these projects. Meetings with these PWS systems have been held and additional meetings to discuss protection measures are intended. The state is also participating in a national pilot project to address the integration of the SDWA and the CWA.

Table IV summarizes the different groundwater protection programs and activities in Mississippi. The following abbreviations listed in the table correspond to the state agencies responsible for the various ground water protection programs:

1. MEMA - Mississippi Emergency Management Agency
2. MDEQ - Mississippi Department of Environmental Quality
3. MDAC - Mississippi Department of Agriculture and Commerce
4. MSDH - Mississippi State Department of Health
5. MSOGB- Mississippi State Oil and Gas Board

Investigations Supporting Groundwater Protection

Because Mississippians are so reliant on the groundwater resources in the state, a great deal of time and effort has been devoted to developing a working knowledge of the related hydrogeology. Agencies that have been involved in groundwater investigations and publications in the past include the U.S. Geological Survey and MDEQ's Office of Land and Water Resources (OLWR) and Office of Geology (OG).

Office of Land and Water Resources

The abundant water supplies in Mississippi constitute one of the most important and valuable natural resources in the state. These resources attribute directly to the quality of life and economic prosperity of the state. However, the water resources available in areas of the state can vary significantly depending on various hydrogeologic conditions that may affect baseflow in streams, water quality, as well as the prolificacy of local aquifers. The highly variable nature of these resources means that a concerted effort must be maintained to collect related groundwater and surface water data that will allow proper decisions to be made regarding the management and development of the state's water resources.

In 2011, work began on a project to evaluate the availability of groundwater resources in Lafayette County. This project continued during 2012, focused upon subsurface occurrence and extent of the aquifer, and collecting water-level data from wells. Also begun in 2011 was a project funded by the United States Geological Survey to evaluate the suitability of the Tuscaloosa group as a repository for the geo-sequestration of carbon dioxide in several counties of southern Mississippi.

The staff of the Office of Land and Water Resources (OLWR) has completed work on the development of a numerical groundwater flow model of the Mississippi River Valley alluvial aquifer (MRVA) of the Delta of northwestern Mississippi. This aquifer is the primary source of water that supports large-scale agricultural activities and aquaculture in that region. The model is being used to better understand the groundwater flow system and the potential effects of variations in pumping patterns. Currently work is being conducted to refine elements of the model.

In the southern third of Mississippi, sand beds of the Catahoula, Hattiesburg, Pascagoula, and Graham Ferry Formations form the main aquifers that are primary sources of water supplies. These formations contain numerous inter-bedded layers of sand and clay. The complexity of these sediments has made it difficult to map the surface geology and delineate the aquifers in the subsurface. The MDEQ Office of Geology and OLWR continued their work in this area to map the surficial geology and construct geologic cross-sections across the area. The

objectives of this effort are to identify and protect the recharge areas of the aquifers that are sources of water in this region and to correlate and determine the extent of the sand intervals that form these aquifers in the subsurface. In 2012 this effort concentrated on Wilkinson and Amite Counties since that area is the focus of significant oil and gas activity in the Tuscaloosa marine shale.

Water Resource Issues in the Mississippi Delta

The economy of the Delta is dependent to a large extent on the availability of suitable water supplies from an estimated 17,000 large-capacity irrigation and aquaculture wells used throughout the region. Most of the water used for these beneficial purposes in the Delta is obtained from the shallow Mississippi River Valley alluvial aquifer (MRVA). With an average withdrawal of approximately 1.5 billion gallons of groundwater pumped per day, the pumpage demand has exceeded the recharge to the MRVA resulting in notable water-level declines in the aquifer. The impacts are much more pronounced in the central portion of the Delta, but the trends indicate that a Delta-wide initiative to conserve water and to balance water use between surface water and groundwater is needed to stabilize the trend. Progress continues to be made on water conservation efforts that began a few years ago, to the point that today, it is widespread throughout the region. To help alleviate extremely low flows in the upper reaches of the Sunflower River, the Yazoo-Mississippi Delta Joint Water Management District maintains a low-flow augmentation project on this stream during dry times of the year.

Several years ago staff from the Office of Land and Water Resources (OLWR) began a drilling project to learn more about the saturated thickness of the alluvial aquifer in the central Delta. This project will be continued for the foreseeable future.

Another continuing effort is being made by OLWR staff to study and determine the regime of recharge to the alluvial aquifer. This includes investigations to determine the influence of the Mississippi River on the MRVA, as well as studies to learn more about the recharge from the bluff hills to the MRVA. OLWR staff continues to drill stratigraphic holes and at certain locations install observation wells to help resolve the recharge dilemma.

Office of Geology

MDEQ's Office of Geology (OG) plays a critical role in supporting the various groundwater investigations in Mississippi. This agency has specialized in the collection of geologic and hydrologic data and provides field support to other divisions of MDEQ. These functions revolve around the OG's drilling rig, coring equipment, and geophysical well-logging units. Water wells and engineering test holes drilled across the state are logged by the staff to collect valuable

hydrogeologic information. These logs are maintained in the OG's log library of water wells and test holes. The work normally associated with a traditional state geological survey is performed by this office. Among the other functions of the agency are surface geologic mapping and research involving the geology, paleontology, and mineral resources of the state.

The preparation of surficial geologic maps by the OG is an important groundwater protection tool that cannot be over emphasized. These maps provide basic information required to assess the availability of energy and mineral resources, locations of geologic hazards, the occurrence and availability of water resources, and the suitability of land for various uses. Geologic maps also are used to characterize sites for waste disposal facilities and to identify aquifer recharge areas.

U. S. Geological Survey

Harrison County Study – The USGS is involved in a project that includes monitoring groundwater changes in the region and analyzing water samples collected from 25 wells in Harrison County annually. Analyses of temperature, pH, specific conductance, color, and concentrations of chloride and manganese are performed as part of this project. Over a 4-year period, the entire network of about 100 wells in Harrison County is sampled and monitored. This project, designed to help protect the local groundwater resources by monitoring for occurrences of saltwater encroachment in the area, is funded via a cooperative agreement with the Harrison County Board of Development.

Real-Time Monitoring of Water Levels – Water levels are being monitored continuously at three well sites located in Bolivar, Wayne, and Grenada Counties. The wells in Wayne and Grenada Counties are part of the Federal Collection of Basic Record (CBR) Program; the Bolivar County well is part of the USGS's NAWQA Program. The related data are transmitted via satellite and are available real-time (updated every 4 hours) at URL:
<http://waterdata.usgs.gov/ms/nwis/current/?type=gw>

Groundwater Data and Maps Database – The USGS is entering electric log card header information into its GWSI database. This effort includes the scanning of approximately 13,000 E-logs using a Neuralog scanner. A web interface that will allow users to view all pertinent information for a well by “pointing and clicking” on a well-location map is in the final stages of development. Combining the water-quality data with the hydrogeological data will hopefully aid in providing a better understanding of the significance of water-quality changes in individual aquifers and also the differences in water quality among the various aquifers. This correlation should enhance the making of better planning and management decisions.

Computer Groundwater Models – Another important function of the USGS is the development, maintenance, and support of various regional groundwater flow models. These USGS models typically are developed to assist in providing MDEQ and Mississippi’s water management districts with enough information that informed decisions can be made in managing and protecting the groundwater resources of the state. For example, model output can be used by water resource planners as a tool in evaluating well-field development. The Mississippi Embayment Aquifer Study (MERAS) produced a model to assist the groundwater availability of the Mississippi Embayment aquifer system. The study area covers portions of eight states including AL, AR, IL, LA, MS, MO, and TN. For more information on the MERAS project, please visit the project’s web page at the following URL:

<http://waterdata.usgs.gov/PROJECTS/MerasModel.html>

Phosphorus in the Mississippi River Alluvial Aquifer – Previous groundwater studies show that phosphorus in Mississippi River alluvial groundwater is higher than the natural background concentration of 0.03 mg/l in groundwater, and higher than the USEPA desired goal of 0.1 mg/L for phosphorus in streams for the prevention of nuisance plant growth. Groundwater from the aquifer could be contributing to high phosphorus concentration in Mississippi Delta streams during the irrigation season. From June to October 2010, the USGS sampled 42 irrigation wells, 1 abandoned irrigation well, and 3 MDEQ monitoring wells. Phosphorus was detected in all 46 wells at concentrations ranging from 0.12 to 1.2 mg/l with a median concentration of 0.62 mg/l.

AQUIFER SPECIFIC INFORMATION

The following aquifer descriptions were revised in 2005 by the USGS, Jackson, MS, from “Sources For Water Supplies In Mississippi”, which was a cooperative study initially sponsored by the USGS and the Mississippi Research and Development Center.

Note: The Coker aquifer is included in this summary but is not listed here because it does not crop out in Mississippi

Figure 1. Location of outcrop areas for principal aquifers in Mississippi (from Wasson, 1986).

Figure 2. Location of the Mississippi River alluvial aquifer outcrop area and selected wells.

Mississippi River Alluvial Aquifer – Dissolved-solids concentrations generally increase from north to south and from east to west in the Mississippi River alluvial aquifer (Wasson, 1986^a). Chemical analyses from selected freshwater wells (fig. 2) representative of the range of dissolved-solids concentrations found in the Mississippi River alluvial aquifer are listed in table 1.

For all wells screened in the Mississippi River alluvial aquifer, dissolved-solids concentrations ranged from 95 to 949 mg/L (milligrams per liter) with a median value of 344 mg/L (fig. 17); hardness ranged from 2 to 690 mg/L with a median value of 290 mg/L (fig. 18); specific conductance ranged from 104 to 1,790 $\mu\text{S}/\text{cm}$ (microsiemens per centimeter) with a median value of 580 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 6.0 to 8.9 standard units with a median value of 7.2 standard units (fig. 19); color ranged from 0 to 55 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from <0.010 to 15 mg/L with a median value of 5.4 mg/L (fig. 20); and nitrate ranged from 0.08 to 12 mg/L with a median value of 0.2 mg/L (fig. 20).

Figure 3. Location of the Citronelle aquifers outcrop area and selected wells.

Citronelle Aquifers – Dissolved-solids concentrations generally increase from north to south in the Citronelle aquifers toward the Gulf of Mexico (Wasson, 1986), except for locations contaminated with brine from oil wells. Chemical analyses from selected freshwater wells (fig. 3) representative of the range of dissolved-solids concentrations found in the Citronelle aquifers are listed in table 2. The downdip limit of freshwater in the Citronelle aquifers is not shown in figure 3, as it may extend several miles beyond the coast line.

For all wells screened in the Citronelle aquifers, dissolved-solids concentrations ranged from 12 to 1,690 mg/L with a median value of 50 mg/L (fig. 17); hardness ranged from 1 to 530 with a median value of 9 mg/L (fig. 18); specific conductance ranged from 13 to 7,200 $\mu\text{S}/\text{cm}$ with a median value of 40 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 4.1 to 10.3 with a median value of 5.4 standard units (fig. 19); color ranged from 0 to 140 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from <0.010 to 2.5 mg/L with a median value of 0.020 mg/L (fig. 20); and nitrate ranged from 0.01 to 37 mg/L with a median value of 1.5 mg/L (fig. 20).

Figure 4. Location of the Miocene aquifer system outcrop area and selected wells.

Miocene Aquifer System – Generally, dissolved-solids concentrations increase with depth in water-bearing units in the Miocene aquifer system and increase downdip from areas of outcrop and recharge (Wasson, 1986). Wells less than 200 feet deep generally yield water with dissolved solids less than 100 mg/L, except where contaminated with brine from oil wells (Kalkhoff, 1982^a). Also, the freshwater section of the Miocene aquifer system is more than 1,000 feet thick, and in some cases, more than 3,000 feet (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 4) representative of the range of dissolved-solids concentrations (but less than 1,000 mg/L) found in the Miocene aquifer system are listed in table 3.

For all wells screened in the Miocene aquifer system, dissolved-solids concentrations ranged from 8 to 130,000 mg/L with a median value of 192 mg/L (fig. 17); hardness ranged from 1 to 3,200 with a median value of 11 mg/L (fig. 18); specific conductance ranged from 16 to 150,000 $\mu\text{S}/\text{cm}$ with a median value of 340 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 4.2 to 9.9 standard units with a median value of 8.0 standard units (fig. 19); color ranged from 0 to 300 platinum-cobalt units with a median value of 7 platinum-cobalt units (fig. 19); iron ranged from <0.010 to 5.1 mg/L with a median value of 0.03 mg/L (fig. 20); and nitrate ranged from 0.04 to 52 with a median value of 0.3 mg/L (fig. 20).

Figure 5. Location of the Oligocene aquifer system outcrop area and selected wells.

Oligocene Aquifer System – Dissolved-solids concentrations generally increase from north to south in the Oligocene aquifer system. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 5) ranges from about 15 miles near the Mississippi-Alabama boundary to about 35 miles in west-central Mississippi (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 5) representative of the range of dissolved-solids concentrations (but less than 1,000 mg/L) found in the Oligocene aquifer system are listed in table 4.

For all wells screened in the Oligocene aquifer system, dissolved-solids concentrations ranged from 40 to 1,480 mg/L with a median value of 323 mg/L (fig. 17); hardness ranged from 3 to 470 mg/L with a median value of 27 mg/L (fig. 18); specific conductance ranged from 46 to 2,430 $\mu\text{S}/\text{cm}$ with a median value of 429 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.3 to 8.8 standard units with a median value of 7.9 standard units (fig. 19); color ranged from 0 to 320 platinum-cobalt units with a median value of 10 platinum-cobalt units (fig. 19); iron ranged from <0.010 to 9 mg/L with a median value of 0.14 mg/L (fig. 20); and nitrate ranged from 0.1 to 7.5 mg/L with a median value of 0.2 mg/L (fig. 20).

Table 4. Typical water-quality data for freshwater wells completed in the Oligocene aquifer system

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in microsiemens per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter; Ca, calcium; Mg, magnesium; Na, sodium; K, potassium; HCO₃, bicarbonate; SO₄, sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃, nitrate; NA, FH, Forest Hill; V, Vicksburg; no data]

Figure 6. Location of the Cockfield aquifer outcrop area and selected wells.

Cockfield Aquifer – Dissolved-solids concentrations generally increase from northeast to southwest in the Cockfield aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 6) ranges from about 20 miles near the Mississippi-Alabama boundary to about 60 miles in west-central Mississippi (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 6) representative of the range of dissolved-solids concentrations found in the Cockfield aquifer are listed in table 5.

For all wells screened in the Cockfield aquifer, dissolved-solids concentrations ranged from 39 to 2,800 mg/L with a median value of 415 mg/L (fig. 17); hardness ranged from 1 to 430 mg/L with a median value of 10 mg/L (fig. 18); specific conductance ranged from 39 to 5,120 $\mu\text{S}/\text{cm}$ with a median value of 700 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.7 to 9.0 standard units with a median value of 8.0 standard units (fig. 19); color ranged from 0 to 1,000 platinum-cobalt units with a median value of 40 platinum-cobalt units (fig. 19); iron ranged from 0.010 to 14 mg/L with a median value of 0.16 mg/L (fig. 20); and nitrate ranged from 0.1 to 5.6 mg/L with a median value of 0.6 mg/L (fig. 20).

Table 5. Typical water-quality data for freshwater wells completed in the Cockfield aquifer

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in micromhos per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter; Ca, calcium, Mg, magnesium, Na, sodium; K, potassium; HCO₃⁻, bicarbonate; SO₄⁻², sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃⁻, nitrate; NA, no data]

Figure 8. Location of the Winona-Tallahatta aquifer outcrop area and selected wells.

Winona-Tallahatta Aquifer– Dissolved-solids concentrations generally increase from northeast to southwest in the Winona-Tallahatta aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 8) ranges from about 20 miles near the Mississippi-Alabama boundary to about 70 miles in west-central Mississippi (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 8) representative of the range of dissolved-solids concentrations found in the Winona-Tallahatta aquifer are listed in table 7.

For all wells screened in the Winona-Tallahatta aquifer, dissolved-solids concentrations ranged from 70 to 1,030 mg/L with a median value of 281 mg/L (fig. 17); hardness ranged from 2 to 170 mg/L with a median value of 10 mg/L (fig. 18); specific conductance ranged from 28 to 2,150 $\mu\text{S}/\text{cm}$ with a median value of 391 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.6 to 8.8 standard units with a median value of 7.7 standard units (fig. 19); color ranged from 0 to 240 platinum-cobalt units with a median value of 16 platinum-cobalt units (fig. 19); iron ranged from 0.010 to 11 mg/L with a median value of 0.12 mg/L (fig. 20); and nitrate ranged from 0.1 to 2.7 mg/L with a median value of 0.5 mg/L (fig. 20).

Table 7. Typical water-quality data for freshwater wells completed in the Winona-Tallahatta aquifer

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in microsiemens per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter: Ca, calcium, Mg, magnesium, Na, sodium; K, potassium; HCO₃, bicarbonate; SO₄ sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃, nitrate; NA, no data]

Figure 9. Location of the Meridian-upper Wilcox aquifer outcrop area and selected wells.

Meridian-upper Wilcox Aquifer— Dissolved-solids concentrations generally increase from northeast to southwest in the Meridian-upper Wilcox aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 9) ranges from about 30 miles near the Mississippi-Alabama boundary to about 90 miles in west-central Mississippi (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 9) representative of the range of dissolved-solids concentrations found in the Meridian-upper Wilcox aquifer are listed in table 8.

For all wells screened in the Meridian-upper Wilcox aquifer, dissolved-solids concentrations ranged from 26 to 1,530 mg/L with a median value of 212 mg/L (fig. 17); hardness ranged from 1 to 1,000 mg/L with a median value of 8 mg/L (fig. 18); specific conductance ranged from 23 to 3,250 $\mu\text{S}/\text{cm}$ with a median value of 307 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.2 to 9.0 standard units with a median value of 7.7 standard units (fig. 19); color ranged from 0 to 200 platinum-cobalt with a median value of 10 platinum-cobalt units (fig. 19); iron ranged from <0.010 to 5.0 mg/L with a median value of 0.12 mg/L (fig. 20); and nitrate ranged from 0.1 to 41 mg/L with a median value of 0.3 mg/L (fig. 20).

Table 8. Typical water-quality data for freshwater wells completed in the Meridian–Upper Wilcox aquifer

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in microsiemens per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter; Ca, calcium, Mg, magnesium, Na, sodium; K, potassium; HCO₃, bicarbonate; SO₄, sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃, nitrate; NA, no data]

Figure 10. Location of the Lower Wilcox aquifer outcrop area and selected wells.

Lower Wilcox Aquifer – Dissolved-solids concentrations generally increase from northeast to southwest in the Lower Wilcox aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 10) ranges from about 50 to 80 miles. Dissolved-solids concentrations are high in the central part of the aquifer where transmissivity values are low (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 10) representative of the range of dissolved-solids concentrations found in the Lower Wilcox aquifer are listed in table 9.

For all wells screened in the Lower Wilcox aquifer, dissolved-solids concentrations ranged from 13 to 4,310 mg/L with a median value of 165 mg/L (fig. 17); hardness ranged from 1 to 130 mg/L with a median value of 16 mg/L (fig. 18); specific conductance ranged from 19 to 7,500 $\mu\text{S}/\text{cm}$ with a median value of 269 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.1 to 8.9 standard units with a median value of 7.5 standard units (fig. 19); color ranged from 0 to 250 platinum-cobalt units with a median value of 7 platinum-cobalt units (fig. 19); iron ranged from 0.010 to 10 mg/L with a median value of 0.14 mg/L (fig. 20); and nitrate ranged from 0.1 to 17 mg/L with a median value of 0.3 mg/L (fig. 20).

Table 9. Typical water-quality data for freshwater wells completed in the Lower Wilcox aquifer

Figure 11. Location of the Ripley aquifer outcrop area and selected wells.

Ripley Aquifer – Dissolved-solids concentrations generally increase from northeast to southwest in the Ripley aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 11) ranges from about 15 to 70 miles (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 11) representative of the range of dissolved-solids concentrations found in the Ripley aquifer are listed in table 10.

For all wells screened in the Ripley aquifer, dissolved-solids concentrations ranged from 34 to 587 mg/L with a median value of 247 mg/L (fig. 17); hardness ranged from 5 to 250 mg/L with a median value of 45 mg/L (fig. 18); specific conductance ranged from 40 to 900 $\mu\text{S}/\text{cm}$ with a median value of 377 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.0 to 8.9 standard units with a median value of 8.1 standard units (fig. 19); color ranged from 0 to 200 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from <0.010 to 5.4 mg/L with a median value of 0.12 mg/L (fig. 20); and nitrate ranged from 0.04 to 4.4 mg/L with a median value of 1.3 mg/L (fig. 20).

Table 10. Typical water-quality data for freshwater wells completed in the Ripley aquifer

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in microsiemens per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter; Ca, calcium, Mg, magnesium, Na, sodium; HCO₃, bicarbonate; SO₄, sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃, nitrate; NA, no data]

Figure 12. Location of the Coffee Sand aquifer outcrop area and selected wells.

Coffee Sand Aquifer – Dissolved-solids concentrations generally increase downdip in the Coffee Sand aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 12) is about 70 miles (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 12) representative of the range of dissolved-solids concentrations found in the Coffee Sand aquifer are listed in table 11.

For all wells screened in the Coffee Sand aquifer, dissolved-solids concentrations ranged from 48 to 495 mg/L with a median value of 190 mg/L (fig. 17); hardness ranged from 5 to 300 mg/L with a median value of 100 mg/L (fig. 18); specific conductance ranged from 40 to 761 $\mu\text{S}/\text{cm}$ with a median value of 280 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.4 to 8.8 standard units with a median value of 7.7 standard units (fig. 19); color ranged from 0 to 15 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from 0.030 to 1.7 mg/L with a median value of 0.080 mg/L (fig. 20); and nitrate ranged from 0.1 to 27 mg/L with a median value of 0.4 mg/L (fig. 20).

Table 11. Typical water-quality data for freshwater wells completed in the Coffee Sand aquifer

Figure 13. Location of the Eutaw-McShan aquifer outcrop area and selected wells.

Eutaw-McShan Aquifer – Dissolved-solids concentrations generally increase downdip in the Eutaw-McShan aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 13) ranges from about 20 miles near the Mississippi-Alabama boundary to about 80 miles in north-central Mississippi (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 13) representative of the range of dissolved-solids concentrations found in the Eutaw-McShan aquifer are listed in table 12.

For all wells screened in the Eutaw-McShan aquifer, dissolved-solids concentrations ranged from 21 to 8,970 mg/L with a median value of 210 mg/L (fig. 17); hardness ranged from 1 to 490 mg/L with a median value of 42 mg/L (fig. 18); specific conductance ranged from 20 to 12,700 $\mu\text{S}/\text{cm}$ with a median value of 260 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 4.1 to 9.2 standard units with a median value of 7.3 standard units (fig. 19); color ranged from 0 to 400 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from 0.010 to 200 mg/L with a median value of 2.5 mg/L (fig. 20); and nitrate ranged from 0.04 to 17 mg/L with a median value of 0.3 mg/L (fig. 20).

*NOTE: High values of iron presented in this figure were closely associated with samples from wells that were shallow (less than 100 foot depth) and that had low pH values (less than 6 standard pH units)

Figure 14. Location of the Gordo aquifer outcrop area and selected wells.

Gordo Aquifer – Dissolved-solids concentrations generally increase downdip in the Gordo aquifer. The distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 14) ranges from 50 to 80 miles (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 14) representative of the range of dissolved-solids concentrations found in the Gordo aquifer are listed in table 13.

For all wells screened in the Gordo aquifer, dissolved-solids concentrations ranged from 21 to 1,380 mg/L with a median value of 104 mg/L (fig. 17); hardness ranged from 3 to 220 mg/L with a median value of 30 mg/L (fig. 18); specific conductance ranged from 24 to 2,390 $\mu\text{S}/\text{cm}$ with a median value of 118 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.0 to 9.6 standard units with a median value of 6.8 standard units (fig. 19); color ranged from 0 to 200 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from 0.010 to 83 mg/L with a median value of 2.9 mg/L (fig. 20); and nitrate ranged from 0.04 to 8.4 mg/L with a median value of 0.2 mg/L (fig. 20).

Table 13. Typical water-quality data for freshwater wells completed in the Gordo aquifer

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in microstemens per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter; Ca, calcium, Mg, magnesium, Na, sodium; HCO₃, bicarbonate; SO₄, sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃, nitrate; NA, no data]

Figure 15. Location of the selected wells in the Coker aquifer.

Coker Aquifer – Dissolved-solids concentrations generally increase downdip in the Coker aquifer. The outcrop of the aquifer is to the east in Alabama, and the distance from the outcrop area to the downdip limit of freshwater (1,000 mg/L dissolved solids, fig. 15) is about 50 miles in the southeastern part of the aquifer (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 15) representative of the range of dissolved-solids concentrations found in the Coker aquifer are listed in table 14.

For all wells screened in the Coker aquifer, dissolved-solids concentrations ranged from 55 to 1,100 mg/L with a median value of 500 mg/L (fig. 17); hardness ranged from 14 to 91 mg/L with a median value of 51 mg/L (fig. 18); specific conductance ranged from 82 to 2,000 $\mu\text{S}/\text{cm}$ with a median value of 905 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 6.0 to 8.5 standard units with a median value of 7.8 standard units (fig. 19); color ranged from 0 to 10 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from 0.16 to 16 mg/L with a median value of 0.97 mg/L (fig. 20); and nitrate ranged from 0.2 to 5.1 mg/L with a median value of 0.8 mg/L (fig. 20).

Table 14. Typical water-quality data for freshwater wells completed in the Coker aquifer

[Depth, well depth in feet below land surface; ROE, residue on evaporation at 180 degrees Celsius, equivalent to total dissolved solids; SC, specific conductance in microsiemens per centimeter at 25 degrees Celsius; pH, standard pH units; color, platinum-cobalt units; all other concentrations in milligrams per liter; Ca, calcium, Mg, magnesium, Na, sodium; HCO₃, bicarbonate; SO₄, sulfate; Cl, chloride; F, fluoride; SiO₂, silica; Fe, iron; NO₃, nitrate; NA, no data]

Figure 16. Location of the Paleozoic aquifer system outcrop area and selected wells.

Paleozoic Aquifer System – Dissolved-solids concentrations generally increase downdip of the top surface in the Paleozoic aquifer system. Dissolved-solids concentrations also increase with depth in the fairly separated aquifers that comprise the Paleozoic aquifer system (Wasson, 1986). Chemical analyses from selected freshwater wells (fig. 16) representative of the range of dissolved-solids concentrations found in the Paleozoic aquifer system are listed in table 15.

For all wells screened in the Paleozoic aquifer system, dissolved-solids concentrations ranged from 39 to 475 mg/L with a median value of 142 mg/L (fig. 17); hardness ranged from 21 to 150 mg/L with a median value of 96 mg/L (fig. 18); specific conductance ranged from 61 to 2,330 $\mu\text{S}/\text{cm}$ with a median value of 296 $\mu\text{S}/\text{cm}$ (fig. 18); pH ranged from 5.2 to 8.2 standard units with a median value of 7.2 standard units (fig. 19); color ranged from 0 to 30 platinum-cobalt units with a median value of 5 platinum-cobalt units (fig. 19); iron ranged from 0.010 to 17 mg/L with a median value of 3.2 mg/L (fig. 20); and nitrate ranged from 0.1 to 0.3 mg/L with a median value of 0.2 mg/L (fig. 20).
